1 Introduction

NOTE: An updated version of this analysis note should be uploaded before 16 December 2016. Amongst other additions, this new version will include more thorough results and discussion of our $\Xi K^{\pm}$ analyses. If possible, we would like to at least show the data from this study, and possibly even preliminary results. However, with QM deadlines close approaching, this may not be possible.

We present results from a femtoscopic analysis of Lambda-Kaon correlations in Pb-Pb collisions at $\sqrt{s_{NN}}$ = 2.76 TeV by the ALICE experiment at the LHC. All pair combinations of Λ and $\bar{\Lambda}$ with K^+, K^- and K^0_S are analyzed. The femtoscopic correlations are the result of strong final-state interactions, and are fit with a parametrization based on a model by R. Lednicky and V. L. Lyuboshitz [**?**]. This allows us to both characterize the emission source and measure the scattering parameters for the particle pairs. We observe a large difference in the Λ-K^+ ($\bar{\Lambda}$-K^-) and Λ-K^- ($\bar{\Lambda}$-K^+) correlations in pairs with low relative momenta ($k^* \lesssim 100$ MeV). Additionally, the average of the Λ-K^+ ($\bar{\Lambda}$-K^-) and Λ-K^- ($\bar{\Lambda}$-K^+) correlation functions is consistent with our Λ-K^0_S ($\bar{\Lambda}$-K^0_S) measurement. The results suggest an effect arising from different quark-antiquark interactions in the pairs, i.e. $s\bar{s}$ in Λ-K^+ ($\bar{\Lambda}$-K^-) and $u\bar{u}$ in Λ-K^- ($\bar{\Lambda}$-K^+). To gain further insight into this hypothesis, we currently are conducting a Ξ-K femtoscopic analysis.
