

0.1 Non-Flat Background

We observe a significant non-femtoscopic, non-flat, background in all of our correlations at large k^* . This background increases with decreasing centrality, is the same amongst all ΛK^\pm pairs, and is more pronounced in the ΛK_S^0 system, as can be seen in Fig. 1. Figure 2a shows that THERMINATOR 2 simulation does a good job of describing the difference in backgrounds between ΛK^\pm and ΛK_S^0 .

Before beginning, it is important to note that the difference in ΛK^\pm and ΛK_S^0 backgrounds is due mainly to the difference in kinematic cuts, not due to any interesting physics. Figure 2b shows that, for THERMINATOR simulation, when restrictions are imposed on the p_T of the K_S^0 to more closely match the K^\pm cuts, the backgrounds align much better. Therefore, we conclude that the difference in background between ΛK^\pm and ΛK_S^0 observed in our experimental data is simply due to a difference in kinematic cuts between K^\pm and K_S^0 particles.

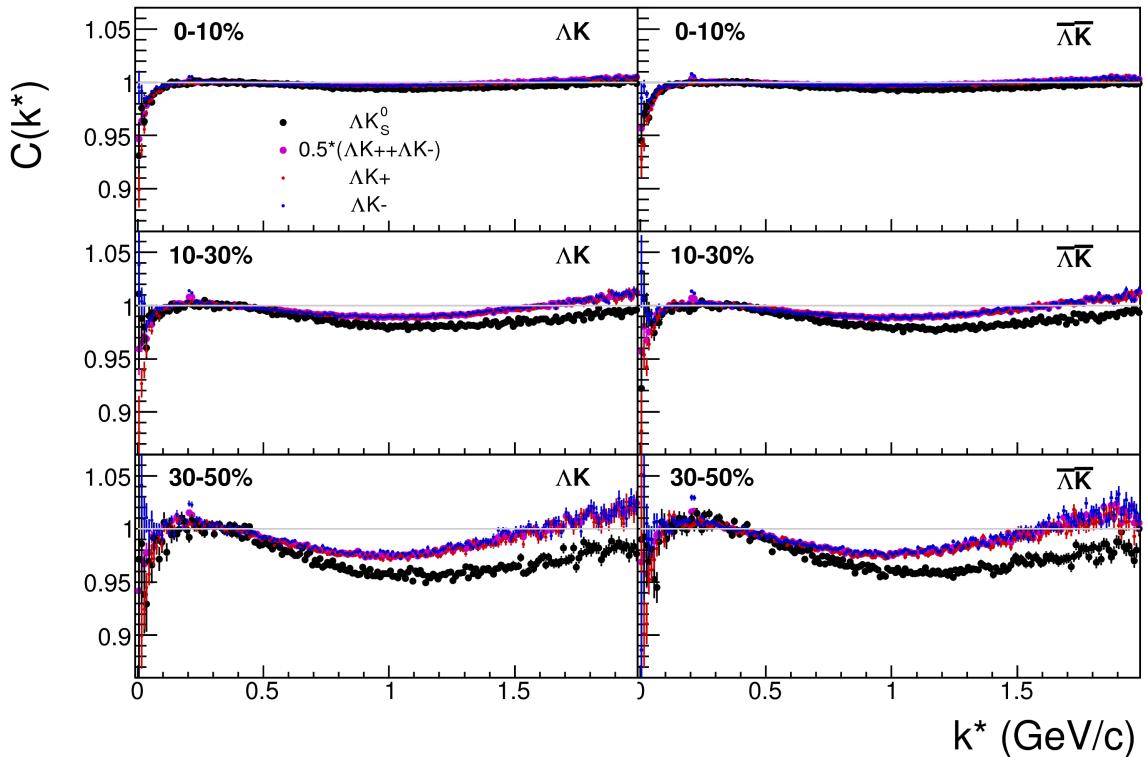

Fig. 1: A comparison on the non-femtoscopic backgrounds observed in our our ΛK experimental data.

It is suggested that this background effect is due primarily to particle collimation associated with elliptic flow [?]. More specifically, these backgrounds result from mixing events with unlike event-plane angles (Ψ_{EP}). As explained in [?], when elliptic flow is present, all particles are more likely to be emitted in a specific direction (in-plane), as opposed to a perpendicular direction. Therefore, the difference in momenta for pairs of particles tends to be smaller, compared to the case of no flow. In the case of mixed-event pairs, the two events used do not share an event-plane, and therefore there is no collimation effect in the pairs from flow. As a result, pairs with larger momentum are more likely when mixed-events are used (in the denominator of the correlation function), causing the correlation function to dip below unity. In general, the observation of the correlation function below unity, at a given k^* , means it is more probable to find a pair at that k^* when the daughters are taken from mixed-events, as compared to when they are taken from the same event. This same reasoning suggests that the background should lead to an enhancement at low- k^* . The enhancement at high- k^* ($k^* \gtrsim 1.5$ GeV/c) does not result from the collective flow of the system. We are not certain what causes this enhancement, but typical suspects are jet-like

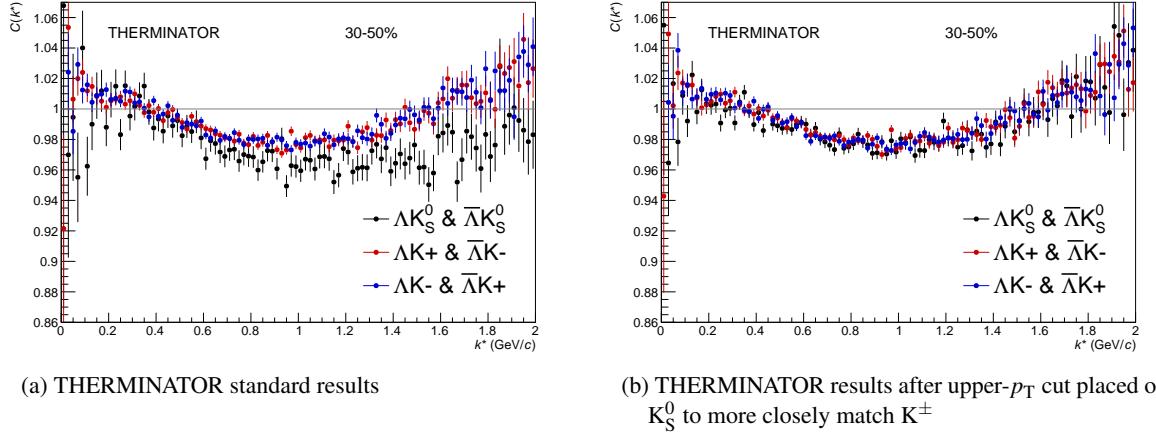

Fig. 2: THERMINATOR 2 simulation for ΛK^+ (red), ΛK^- (blue), and ΛK_S^0 (black). In 2a, we show the standard THERMINATOR 2 results. THERMINATOR 2 does a good job describing qualitatively the different between the ΛK^\pm and ΛK_S^0 backgrounds. In 2b, an upper- p_T cut was placed on the K_S^0 particles to more closely match the K^\pm kinematic cuts. After this tweak, the ΛK^\pm and ΛK_S^0 backgrounds agree much better.

correlations and resonance decays.

We can split our correlation functions into three main regions. First, the low- k^* region ($k^* \lesssim 0.3$ GeV/ c) contains the femtoscopic correlations, as well as a likely enhancement from the background. The intermediate- k^* region ($0.3 \lesssim k^* \lesssim 1.5$ GeV/ c) contains a suppression from the background. Finally, the high- k^* region ($k^* \gtrsim 1.5$ GeV/ c) contains an enhancement with unknown origin.

The issue here is that we need to know the behavior of the non-femtoscopic background in the low- k^* region, but we only cleanly observe it in the region further out where there is no femtoscopic signal. Unfortunately, we cannot simply rotate each event to artificially align their event-planes and rid ourselves of this mixing effect, as our azimuthal angle acceptance is not perfectly uniform, and we have only finite event-plane resolution. With better resolution, one could simply bin events in Ψ_{EP} and only mix events within a given bin. We pursued this direction, and observed a slight decrease in the background; however, going to finer binning, we saw no additional reduction in the background, signaling that we had reached the limits dictated by the resolution. In the end, we are forced to model the background to include it into our fit.

THERMINATOR 2 simulation has been shown to reproduce the background features in a πK analysis [?]. After issuing each simulated event a random Ψ_{EP} ¹, we found THERMINATOR 2 did an exceptional job of describing our data. Furthermore, the simulation showed the non-femtoscopic background affects the correlation function as a separable scale factor (Fig 4, discussed below). Figure 3 shows the THERMINATOR 2 simulation (gold) together with experimental data (red, blue, or black). The figure also shows a 6th-order polynomial fit to the simulation (gold), as well as the fit polynomial scaled to match the data (red, blue, black).

Figure 4 shows three different correlation function generated using THERMINATOR 2 simulation (“Cf w/o Bgd (A)”, “Cf w. Bgd (B)”, “Bgd(C)”), as well as two histograms describing the relation between the three (“Ratio (B/C)”, “1+Diff(B-C)”). “Cf w/o Bgd (A)” shows a correlation function with a femtoscopic correlation, but without background. When THERMINATOR 2 is run without randomizing event planes, and therefore having all events share a common event plane, no background is observed, as expected. The femtoscopic correlation effect was introduced by assuming a set of scattering parameters for

¹default was for all events to share a common event plane

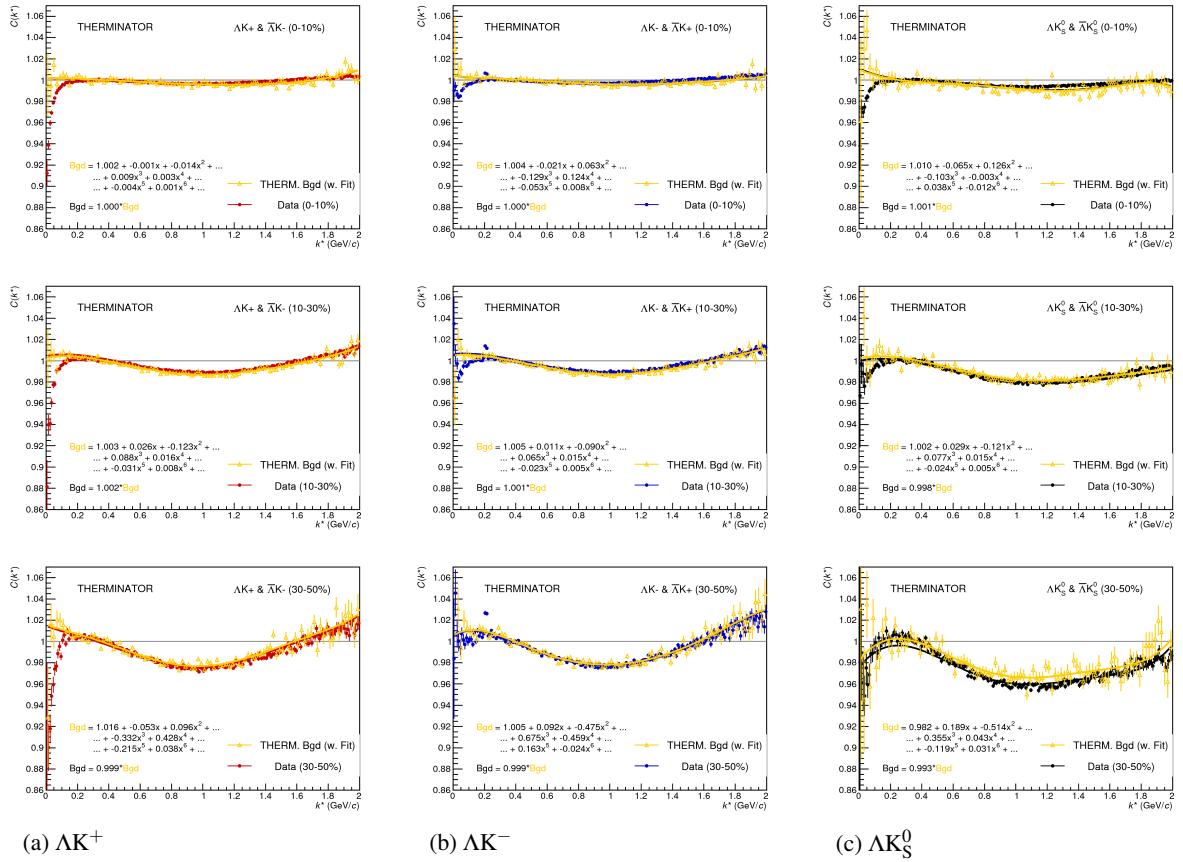

Fig. 3: THERMINATOR 2 simulation (gold) together with experimental data (red, blue, or black). The left column shows results for ΛK^+ (3a), middle for ΛK^- (3b), and right for ΛK_S^0 (3c). A 6th-order polynomial fit to the simulation is shown as a solid gold line, and whose fit parameters are printed on the lower left of each plot. This polynomial is scaled to match the experimental data; the value of this scale is printed in the lower left corner of each plot. The polynomial fit with scale factor applied is drawn in a color matching the experimental data (red, blue, black).

the system, and weighting the numerators appropriately. The second correlation, "Cf w. Bgd (B)", shows a correlation function with both a femtoscopic correlation and a background (most closely matches our situation in experiment). To generate the background, each event was given a random event-plane angle, as is given to us in experiment. To generate the femtoscopic correlation, the same numerator weighting procedure was used. Finally, "Bgd (C)", shows a correlation function with a non-femtoscopic background, but no femtoscopic correlation, i.e. background only. This is generated just as "Cf w. Bgd (B)", with randomized event planes, but unit weights are used when filling the numerators, so no femtoscopic effects are included.

The main point of Fig. 4 is that the black points match the blue (and purple) points; or, equivalently:

$$C_{fw/oBgd} = \frac{C_{fw.Bgd}}{Bgd} \rightarrow C_{theory} = \frac{C_{exp}}{F_{Bgd}} \rightarrow C_{exp} = C_{theory} \cdot F_{Bgd} \quad (1)$$

i.e. THERMINATOR 2 simulation shows the non-femtoscopic background affects the correlation function as a separable scale factor. We expect this behavior to be roughly the same in the experimental data.

Figure 5 demonstrates the use of the Stavinskiy method with THERMINATOR 2. In the figure, unit

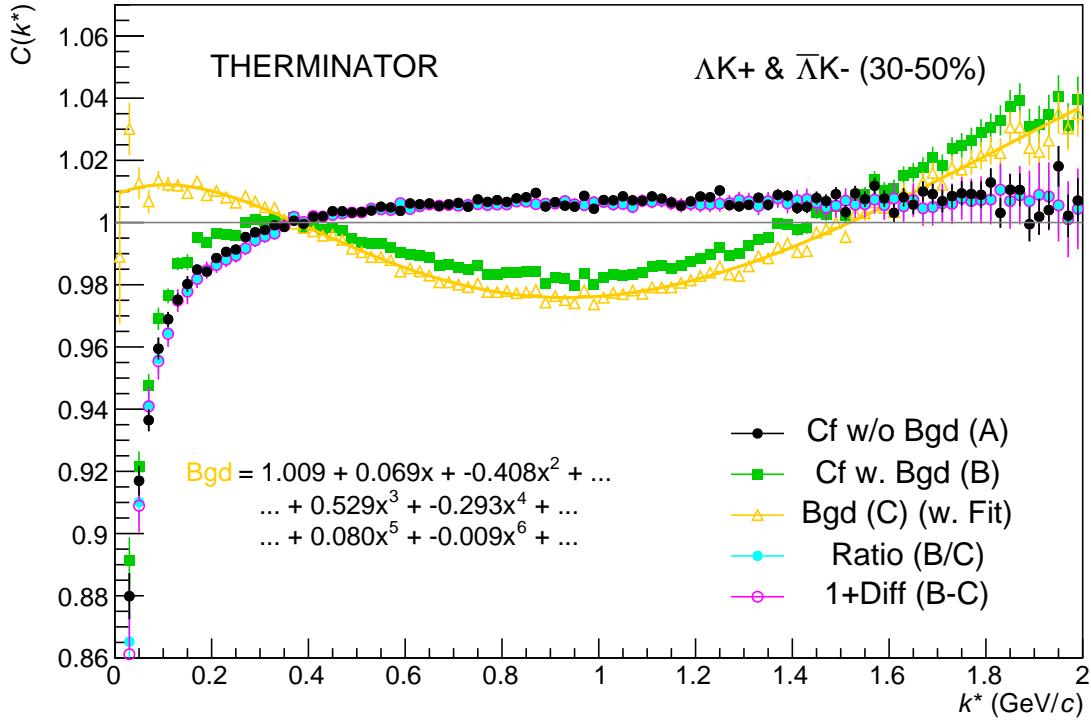

Fig. 4: Correlation with background decomposition with THERMINATOR. "Cf w/o Bgd (A)" shows a correlation function with a femtoscopic correlation, but without background. "Cf w. Bgd (B)", shows a correlation function with both a femtoscopic correlation and a background (most closely matches our situation in experiment). "Bgd (C)", shows a correlation function with a non-femtoscopic background, but no femtoscopic correlation, i.e. background only.

weights were used for all numerators, so no femtoscopic signal is included, only background effects. The black points show an ideal, experimentally unreachable, situation of aligning all of the event-plane angles. With THERMINATOR 2, when the event-planes are aligned, the background signal is killed. The green points show the case of random event-plane angles, a situation more closely matching that of experiment. The purple points shown the affect of applying the Stavinskiy method to the case of random event-planes. The figure shows that this method effectively kills the non-flat background (i.e. the procedure takes the green points to the purple). Finally, the blue points show the effect of applying the Stavinskiy method when all of the event-planes are aligned. This shows that the Stavinskiy method does not introduce any signal to an already flat background.

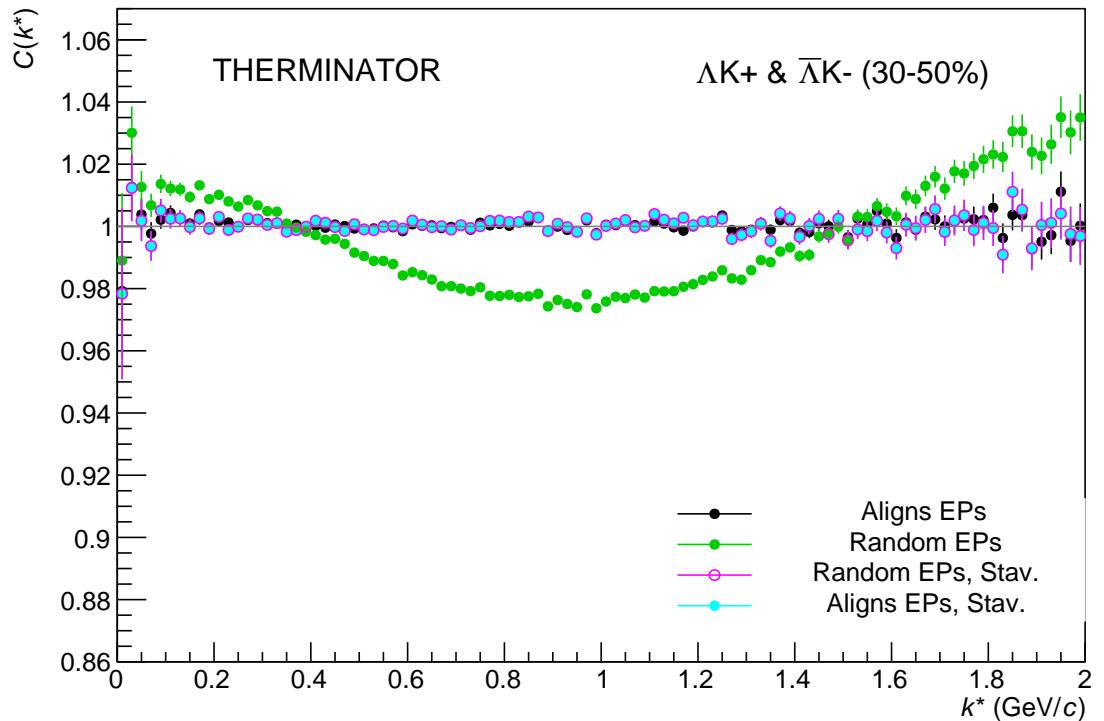

Fig. 5: The use of the Stavinskiy method with THERMINATOR 2. Unit weights were used for all numerators, so no femtoscopic signal is included, only background effects. The black points show an ideal, experimentally unreachable, situation of aligning all of the event-plane angles. The green points show the experimental situation of random event-plane angles. The purple points shown the affect of applying the Stavinskiy method to the case of random event-planes. Finally, the blue points show the effect of applying the Stavinskiy method when all of the event-planes are aligned.
